# IDENTIFICATION AND FUNCTIONAL CHARACTERIZATION OF A NOVEL RIBOSOMAL S6 PROTEIN KINASE

5

This invention relates to United States Provisional Application Serial No. 60/095,268, filed August 4, 1988, which is incorporated by reference herein in its entirety.

10

### FIELD OF THE INVENTION

The present invention relates to a novel S6 kinase (p70β<sup>Sk6</sup>), mutant variants thereof, methods of making and using this S6 kinase, and related nucleic acids and antibodies. The invention also relates to binding partners of the S6 kinase, methods of 15 identifying the binding partners and antibodies thereto.

# BACKGROUND OF THE INVENTION

The 40S ribosomal protein S6 is a component of the 40S subunit of eukaryotic ribosomes. The ribosomes are part of the cellular machinery responsible for translation 20 of mRNA and protein synthesis. The S6 protein is phosphorylated in response to certain cellular signaling events such as hormone or growth factor induced cellular proliferation. p70 S6 kinase (p70<sup>S6k</sup>) is responsible for S6 phosphorylation and is believed to be the major physiological S6 kinase in mammalian cells (Proud, 1996 Trends Biochem. Sci. 21: 181-185).

25

#### p70α S6 Kinase 1.

#### Structure and Function A.

The first p70 S6 kinase identified was the alpha (a) form. The gene encoding the human p70α S6 kinase (p70<sup>S6k</sup>)was isolated in 1991 (Grove et al., 1991 Mol. Cell. Biol. 11: 5541-5550). Other p70α S6 kinase sequences have been described in *Mus musculus* (GenBank Accession No. SEG\_AB015196S, AB015197, and AB015196), *Xenopus laevis* (GenBank Accession No. X66179), and rat (GenBank Accession No. M57428).

- Two p70α S6 kinase isoforms were identified: p70α-I (GenBank Accession No. M60724) and p70α-II (GenBank Accession No. M60725). The two p70α S6 kinase isoforms differ only in their amino termini by 23 amino acid residues resulting in a 70 kD protein and a 85 kD protein. The isoforms are referred to in the literature as p70<sup>S6k</sup>/p85<sup>S6k</sup> or p70α S6 kinase. Both isoforms share similar activity towards
  10 ribosomal protein S6 *in vitro* but are expressed in different cells and tissues. The two isoforms are produced by two mRNA products and are not a result of post-translational modifications. They are serine/threonine kinases and are known to act on the substrate KKRNRTLSVA (SEQ ID No. 7) (Pai *et al.*, 1994 <u>Eur. J. Immunol.</u> 24: 2364-8; and Leighton *et al.*, 1995 <u>FEBS Letters</u> 375: 289-93).
- The p70α S6 kinase plays an important role in the progression of cells from G1 to S phase of the cell cycle and in the initiation of protein synthesis. Recently, p70α S6 kinase has been demonstrated to regulate the translation of a class of mRNAs containing an oligopyrimidine tract in their 5' untranslated region. This class of mRNAs, termed 5'TOP mRNAs, represent up to 20% of the a cell's total mRNA.
- 20 Many of the proteins encoded by 5TOP mRNAs are translational apparatus proteins and cell-cycle progression proteins.

The p70α S6 kinase has four identified interdependent domains: (1) a catalytic domain, (2) a kinase extension domain, (3) a pseudosubstrate autoinhibitory domain, and (4) the N-terminal domain. The catalytic domain is located in the middle of the 25 protein and is followed by the kinase extension domain, which is a unique feature for the PKA family. The pseudosubstrate autoinhibitory domain is also unique for the p70α S6 kinase, not having been observed in any other known kinases. It possesses 5 phosphorylation sites which are responsible for the p70α S6 kinase regulation. The N-terminal domain mediates the sensitivity for rapamycin, which strongly inhibits serum-

induced phosphorylation and activation of the  $p70\alpha$  S6 kinase. This domain may also mediate the interaction with a yet unknown phosphatase.

### B. Regulators and Cascades

- Growth factors, such as insulin, and mitogens are known to activate *in vivo* p70α S6 kinase (Alessi *et al.*, 1998 <u>Curr. Biol.</u> 8: 69-81). Heat shock also activates p70α S6 kinase (Lin *et al.*, 1997 <u>J. Biol. Chem.</u> 272: 31196-31202). Certain drugs have been identified that regulate p70α S6 kinase activity including: rapamycin, wortmannin, Ro31-8220, GF109203X, LY294002, phenylephrine (PE), PD098059, SQ20006,
- polymerized collagen, forskolin, interleukin-10 (IL-10), demethoxyviridin, phorbol 12-myristate 13-acetate (PMA), A23187, bombesin and antibodies which recognize the p70α S6 kinase (Proud, 1996; Morreale et al., 1997 FEBS Letters 417: 38-42; Kanda et al., 1997 J. Biol. Chem. 272: 23347-23353; Boluyt et al., 1997 Circ. Res. 81: 176-186; Coolican et al., 1997 J. Biol. Chem. 272: 6653-6662; Koyama et al., 1996 Cell 87:
- 15 1069-1078; Busca et al., 1996 J. Biol. Chem. 271: 31824-31830; Crawley et al., 1996 J. Biol. Chem. 271: 16357-16362; and Petritsch et al., 1995 Eur. J. Biochem. 230: 431-8). The immunosuppressant rapamycin (Rap) is the most potent inhibitor of p70α S6 kinase described (Pullen et al., 1997 FEBS Letters 410: 78-82).

p70α S6 kinase is an enzyme which lies downstream of phosphoinositide 3-

kinases (PI3-kinase). The mechanisms regulating the p70α S6 kinase have not been fully elucidated. PI3-kinase has recently been shown to activate another phosphoinositide-dependent protein kinase, termed PDK-1. So far, only PDK-1 has been shown to phosphorylate p70α S6 kinase *in vivo*, and this phosphorylation is essential for p70α<sup>S6k</sup> activity towards ribosomal S6 protein. Wortmannin, a fungal

25 inhibitor which down-regulates the p70α S6 kinase, is believed to act by inhibiting PI-3 kinase. In contrast, another fungal inhibitor, rapamycin, inhibits the p70α S6 kinase by another cascade pathway involving the mammalian target of rapamycin (mTOR; also known as RAFT or FRAP) (Proud, 1996; Stewart et al., 1994 <u>BioEssays</u> 16: 809-815). mTOR is a member of the PIK-related family of protein kinases (Pullen et al., 1997).

Additional regulators of the p70 $\alpha$  S6 kinase include, but are not limited to protein kinase B (PKB), Cdc42, and Rac. The role of most of these proteins as p70 $\alpha$  S6 kinase regulators has yet to be fully elucidated.

5

#### SUMMARY OF THE INVENTION

The present invention is based on our discovery of a new gene which encodes a novel S6 kinase (p70β<sup>S6k</sup>). The invention includes isolated nucleic acid molecules selected from the group consisting of an isolated nucleic acid molecule that encodes the amino acid sequence of SEQ ID No.2, (e.g., SEQ ID No.1) an isolated nucleic acid molecule that encodes a fragment of SEQ ID No.2, an isolated nucleic acid molecule which hybridizes to the complement of a nucleic acid molecule comprising SEQ ID No.1 under conditions of sufficient stringency to produce a clear signal and an isolated nucleic acid molecule which hybridizes to the complement of a nucleic acid molecule that encodes the amino acid sequence of SEQ ID No.2 under conditions of sufficient stringency to produce a clear signal.

The present invention further includes the nucleic acid molecules operably linked to one or more expression control elements, including vectors comprising the isolated nucleic acid molecules. The invention further includes host cells transformed to contain the nucleic acid molecules of the invention and methods for producing a protein comprising the step of culturing a host cell transformed with the nucleic acid molecule of the invention under conditions in which the protein is expressed.

The invention further provides an isolated polypeptide selected from the group consisting of an isolated polypeptide comprising the amino acid sequence of SEQ ID No.2, an isolated polypeptide comprising a fragment of SEQ ID No.2, an isolated polypeptide comprising conservative amino acid substitutions of SEQ ID No.2 and naturally occurring amino acid sequence variants of SEQ ID No.2.

The invention further provides an isolated antibody that binds to a polypeptide of the invention, including monoclonal and polyclonal antibodies and fragments

thereof.

20

The invention further provides methods of identifying an agent which modulates the expression of a nucleic acid encoding the protein having the sequence of SEQ ID No.2 comprising the steps of: exposing cells which express the nucleic acid to 5 the agent; and determining whether the agent modulates expression of said nucleic acid, thereby identifying an agent which modulates the expression of a nucleic acid encoding the protein having the sequence of SEQ ID No.2.

The invention further provides methods of identifying an agent which modulates at least one activity of a protein comprising the sequence of SEQ ID No.2 10 comprising the steps of: exposing cells which express the protein to the agent; and determining whether the agent modulates at least on activity of said protein, thereby identifying an agent which modulates at least one activity of a protein comprising the sequence of SEQ ID No.2.

The invention further provides methods of identifying binding partners for a 15 protein comprising the sequence of SEQ ID No.2 or activated variants thereof, comprising for example, the steps of: exposing said protein to a potential binding partner; and determining if the potential binding partner binds to said protein, thereby identifying binding partners for a protein comprising the sequence of SEQ ID No.2. Exposing may be accomplished by expressing the protein in a cell.

The present invention further provides methods of modulating the expression of a nucleic acid encoding the protein having the sequence of SEQ ID No.2 comprising the step of: administering an effective amount of an agent which modulates the expression of a nucleic acid encoding the protein having the sequence of SEQ ID No.2. The invention also provides methods of modulating at least one activity of a protein 25 comprising the sequence of SEQ ID No.2 comprising the step of: administering an effective amount of an agent which modulates at least one activity of a protein comprising the sequence of SEQ ID No.2.

# BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1. Nucleic acid sequence of p70β<sup>s6k</sup> (SEQ ID No.1) and comparison with p70α<sup>s6k</sup> (SEQ ID No. 3). Sequence analysis of cDNA encoding the p70β S6 kinase. p70β cDNA may encode two isoforms with the use of alternative start codon. The longer form may encode a protein of 495 amino acid residues and the shorter form,
5 482 amino acids (aa). Alternative start codons and a stop codon are highlighted.

  - Figure 3A. Nylon membrane containing 2  $\mu g$  of gel-separated, pre-bound poly(A)+ RNA samples from various human tissues was hybridized with cDNA fragments of p70 $\alpha^{S6k}$ , p70 $\beta^{S6k}$  or  $\beta$ -actin labeled by random priming. The upper, middle and lower panels are autoradiographs probed with p70 $\beta^{S6k}$ , p70 $\alpha^{S6k}$  and  $\beta$ -actin,
- respectively. Each lane contains mRNA prepared from: heart (lane 1), brain (lane 2), placenta (lane 3), lung (lane 4), liver (lane 5), skeletal muscle (lane 6), kidney (lane 7), pancreas (lane 8), spleen (lane 9), thymus (lane 10), prostate (lane 11), testis (lane 12), ovary (lane 13), small intestine (lane 14), mucosal lining of the colon (lane 15), and peripheral blood leukocytes (lane 16).
- Figure 3B. Nylon membrane containing 2 μg of mRNA isolated from tumor cell lines was probed with the 3' cDNA fragment from p70β<sup>S6k</sup>, which was labeled by random-prime labeling. Specific binding was determined by autoradiography. Promyelocytic leukemia HL-60 (lane 1), HeLa cell S3 (lane 2, chronic myelogenous leukemia K562 (lane 3), lymphoblastic leukemia MOLT-4 (lane 4), Burkitt's

lymphoma Raji (lane 5), colorectal adenocarcinoma SW480 (lane 6), lung carcinoma (lane 7), and melanoma G361 (lane 8).

Figure 4A - 4B. Phosphorylation of the ribosomal protein S6 (Figure 4A) and
its C-terminal synthetic peptide (Figure 4B) by p70α<sup>S6k</sup> and p70β<sup>S6k</sup>. Ribosomal S6 protein (purified ribosomal 40S subunits from liver) and synthetic peptides corresponding to the S6 protein C-terminus (e.g., KEAKEKRQEQIARRRLSSLRASTSKSESSQK-long form (SEQ ID No. 5) and RRRLSSLRASTSKSESSQK-(SEQ ID No. 6) short form) were used to measure the
activity of the p70α<sup>S6k</sup> and p70β<sup>S6k</sup>. HEK293 cells were transfected with plasmids containing Flag-tag or EE-tag versions of p70α<sup>S6k</sup> or p70β<sup>S6k</sup>. Recombinant proteins were immunoprecipitated with anti-EE or anti-Flag antibodies and an in vitro kinase reaction performed in the presence of the ribosomal 40S subunits or synthetic peptides. After SDS-PAGE analysis, phosphorylation of the S6 protein and synthetic peptides
was measured by PhosphoImager and expressed in arbitrary units (PI units).

Figure 5A - 5B. Stimulation of p70β<sup>s6k</sup> Activity by insulin, serum and TPA.

Figure 5A. CHO-IR cells were transfected with mock (lane1) or plasmids

containing cDNAs of FLAG-tagged p70α-I (lanes 2 and 3) or FLAG-tagged p70β-II

20 (lanes 4 to 7). After serum starvation for 16 hrs, cells were treated with the vehicle

(lanes 2 and 4), 10<sup>-7</sup> M insulin for 10 min (lanes 3 and 5), 15% serum for 10 min (lane

6) or 500 nM TPA for 30 min (lane7). After cell lysis and subsequent

immunoprecipitation with anti-FLAG antibodies, immunoprecipitates were subjected

to a p70 S6 kinase assay using 40S subunits as substrates. The reaction mixture was

25 separated by SDS-PAGE, transferred onto PVDF membrane. The membrane was

analyzed by autoradiography (upper panel) and then immunoblotted with anti-FLAG

antibodies (lower panel). A representative of three experiments is shown. <sup>32</sup>P

incorporation into S6 was quantified by Molecular Dynamics PhosphorImager<sup>TM</sup> and is

expressed in arbitrary units (PI units).

Figure 5B. Stimulation of the p70α<sup>S6k</sup> and p70β<sup>S6k</sup> activity towards ribosomal S6 protein by PDGF in PAE-PDGF-R cells. PAE-PDGF-R cells were transfected with EE-tagged p70α<sup>S6k</sup> and p70β<sup>S6k</sup> plasmids using lipofectAMINE. After 24 hr, transfected cells were serum-starved for 16 hr and stimulated with 20 ng/ml PDGF BB (Calbiochem) for 20 min. Control cells were treated with the vehicle under the same conditions. After immunoprecipitation with anti-EE antibodies, an *in vitro* kinase reaction was carried out in the presence of 40S subunits, containing the S6 protein. Reaction mixtures were separated by SDS-PAGE and incorporation of <sup>32</sup>P into S6 protein was measured by PhosphoImager.

10

Figure 6A - 6B. Effects of rapamycin and wortmannin on p70β<sup>S6k</sup> and p70α<sup>S6k</sup>. Effects of rapamycin and wortmannin on S6 phosphorylation activity of p70α-I or p70β-II. HEK293 cells were transfected with mock cDNA or plasmids containing FLAG-tagged p70α1 or p70β2 isoforms. After 48 h of transfection, cells were treated with vehicle or indicated concentrations of rapamycin or wortmannin for 30 min. After immunoprecipitation with anti-FLAG antibodies, the kinase activity was determined by a p70 S6 kinase assay using 40S subunits as substrates. The proteins of the reaction mixture were separated by SDS-PAGE, transferred onto PVDF membrane and analyzed by autoradiography (Figures 6A and 6B, upper panels). Subsequent immunoblotting with anti-FLAG antibody confirmed the expression of p70α-I (Figure 6A, lower panel) and p70β-II (Figure 6B, lower panel). A representative of three experiments is shown.

32P incorporation into S6 was quantified by PhosphorImager and is expressed in arbitrary units (PI units).

Figure 7. Interaction of the p70β<sup>s6k</sup> with different GST/SH3 fusion proteins. HEK293 cells were transiently transfected with EE-tag/p70β<sup>s6k</sup>. Two days later, cells were lysed and the lysates were immunoprecipitated with anti-EE antibodies. GST/SH3 fusion proteins (1.5 μg each) were incubated with anti-EE tag immunoprecipitates. Specific interaction with p70β<sup>s6k</sup> was measured by anti-GST

immunoblotting. SH3 domains from different signaling and cytoskeletal proteins were expressed in bacteria as GST fusion proteins and purified nearly to homogeneity using glutathione-Sepharose beads. The GST/SH3 fusion proteins used are: GST (lane 1), p80α subunit of the PI3-kinase (lane 2), GAP (lane 3), PLCγ (lane 4), spectrin (lane 5), crk (lane 6), n-grb2 (lane 7), c-grb2 (lane 8), grb2 full (lane 9), csk (lane 10), fgr (lane 11), fyn (lane 12), src (lane 13), ruk a (lane 14), ruk b (lane 15), ruk c (lane 16), p15 (lane 17), profilin (lane 18) and GST/GAP control (lane 19). "1" indicates instances of binding between p70β<sup>SGk</sup> and a SH3 containing fusion protein.

Figure 8. Immunoprecipitation and Western blot analysis of the p70β-I and p70β-II isoforms transiently over expressed in HEK293 cells with anti-p70 $\beta$ <sup>56k</sup> antibodies. The lanes are the same for each panel: mock transfected (lane 1), Flag-p70α-I transfected (lane 2), Flag-p70β-I transfected (lane 3), and Flag-p70β-II transfected (lane 4).

  - Figure 12:  $p70\alpha^{S6k}$  (T412D) activity. Activity of  $p70\alpha^{S6k}$  (T412D) variant as compared to wt  $p70\alpha^{S6k}$  under S6 Kinase and autophosphorylation assays.

## 5 DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

The terms "p70 $\alpha$ ", "p70 $\alpha$ <sup>S6</sup>k" and "p70 $\alpha$  S6 kinase" are meant to include the two isoforms, p70 and p85, both of which phosphorylate the ribosomal protein S6. By "p70 $\alpha$ -1" and "p70 $\alpha$ -1" are meant the p85 isoform of the p70 $\alpha$  S6 kinase. By "p70 $\alpha$ -2" and "p70 $\alpha$ -II" are meant the p70 isoform of the p70 $\alpha$  S6 kinase.

The terms "p70 $\beta$ ", "p70 $\beta$ S6k" and "p70 $\beta$ S6 kinase" include the newly identified S6 kinase and all its isoforms.

#### I. General Description

The present invention is based in part on identifying a new gene that encodes a novel S6 kinase (p70 $\beta$ <sup>S6k</sup>). This new gene and the protein that it encodes are members of the family of S6 kinases, of which the p70 $\alpha$ -I and -II (also referred to as p70 $\alpha$ -1 and p70 $\alpha$ -2) isoforms have already been reported.

The protein can serve as a target for agents that can be used to modulate the expression or activity of the protein. For example, agents may be identified which 20 modulate biological processes associated with ribosomal activity.

The present invention is further based on the development of methods for isolating binding partners that bind to the protein or its activated variants. Probes based on the protein are used as capture probes to isolate potential binding partners, such as other proteins. Dominant negative proteins, DNAs encoding these proteins, antibodies to these proteins, peptide fragments of these proteins or mimics of these proteins may be introduced into cells to affect function. Additionally, these proteins provide a novel target for screening of synthetic small molecules and combinatorial or naturally occurring compound libraries to discover novel therapeutics to regulate ribosomal function.

15

20

#### II. Specific Embodiments

#### A. The Ribosome Associated Protein

The present invention provides isolated protein, allelic variants of the protein, and conservative amino acid substitutions of the protein, including substitutions that 5 activate the protein. As used herein, the protein or polypeptide refers to a protein that has the human amino acid sequence of depicted in SEQ ID No.2. The invention includes naturally occurring allelic variants and proteins that have a slightly different amino acid sequence than that specifically recited above. Allelic variants, though possessing a slightly different amino acid sequence than those recited above, will still 10 have the same or similar biological functions associated with the disclosed protein.

As used herein, the family of proteins related to the disclosed protein refer to proteins that have been isolated from organisms in addition to humans. The methods used to identify and isolate other members of the family of proteins related to the disclosed protein are described below.

The proteins of the present invention are preferably in isolated form. As used herein, a protein is said to be isolated when physical, mechanical or chemical methods are employed to remove the protein from cellular constituents that are normally associated with the protein. A skilled artisan can readily employ standard purification methods to obtain an isolated protein.

The proteins of the present invention further include conservative variants of the proteins herein described. As used herein, a conservative variant refers to alterations in the amino acid sequence that do not adversely affect the biological functions of the protein. A substitution, insertion or deletion is said to adversely affect the protein when the altered sequence prevents or disrupts a biological function associated with the 25 protein. For example, the overall charge, structure or hydrophobic/hydrophilic properties of the protein can be altered without adversely affecting a biological activity. Accordingly, the amino acid sequence can be altered, for example to render the peptide more hydrophobic or hydrophilic, without adversely affecting the biological activities of the protein. Conservative substitutions may irreversibly activate the protein.

Ordinarily, the allelic variants, the conservative substitution variants, the members of the protein family, will have an amino acid sequence having at least 71%-about 75% amino acid sequence identity with the human sequence set forth in SEQ ID No.2, more preferably at least 80%, even more preferably at least 90%, and most preferably at least 95%. Identity or homology with respect to such sequences is defined herein as the percentage of amino acid residues in the candidate sequence that are identical with the known peptides, after aligning the sequences and introducing gaps, if necessary, to achieve the maximum percent homology, and not considering any conservative substitutions as part of the sequence identity. N-terminal, C-terminal or internal extensions, deletions, or insertions into the peptide sequence shall not be construed as affecting homology.

Homology or identity is determined by BLAST (Basic Local Alignment Search Tool) analysis using the algorithm employed by the programs blastp, blastn, blastx, tblastn and tblastx (Karlin, et al. Proc. Natl. Acad. Sci. USA 87: 2264-2268 15 (1990) and Altschul, S. F. J. Mol. Evol. 36: 290-300(1993), fully incorporated by reference) which are tailored for sequence similarity searching. The approach used by the BLAST program is to first consider similar segments between a query sequence and a database sequence, then to evaluate the statistical significance of all matches that are identified and finally to summarize only those matches which satisfy a preselected 20 threshold of significance. For a discussion of basic issues in similarity searching of sequence databases, see Altschul et al. (Nature Genetics 6: 119-129 (1994)) which is fully incorporated by reference. The search parameters for histogram, descriptions, alignments, expect (i.e., the statistical significance threshold for reporting matches against database sequences), cutoff, matrix and filter are at the default settings. The 25 default scoring matrix used by blastp, blastx, tblastn, and tblastx is the BLOSUM62 matrix (Henikoff, et al. Proc. Natl. Acad. Sci. USA 89: 10915-10919 (1992), fully incorporated by reference). For blastn, the scoring matrix is set by the ratios of M (i.e., the reward score for a pair of matching residues) to N USA 87: 2264-2268 (1990) and (i.e., the penalty score for mismatching residues), wherein the default values for M and

N are 5 and -4, respectively.

Thus, the proteins of the present invention include molecules having the amino acid sequence disclosed in SEQ ID No.2; fragments thereof having a consecutive sequence of at least about 3, 5, 10 or 15 amino acid residues of the disclosed protein; 5 amino acid sequence variants of such sequence wherein an amino acid residue has been inserted N- or C-terminal to, or within, the disclosed sequence; amino acid sequence variants of the disclosed sequence, or their fragments as defined above, that have been substituted by another residue. Contemplated variants further include those containing predetermined mutations by, e.g., homologous recombination, site-directed or PCR 10 mutagenesis, and the corresponding proteins of other animal species, including but not limited to rabbit, rat, murine, porcine, bovine, ovine, equine and non-human primate species, and the alleles or other naturally occurring variants of the family of proteins; and derivatives wherein the protein has been covalently modified by substitution. chemical, enzymatic, or other appropriate means with a moiety other than a naturally 15 occurring amino acid (for example a detectable moiety such as an enzyme or radioisotope). Proteins of the invention may include fusion proteins comprising any of the foregoing.

As described below, members of the family of proteins can be used: 1) to identify agents which modulate at least one activity of the protein, including agents which may modulate phosphorylation mediated by the protein; 2) in methods of identifying binding partners for the protein, 3) as an antigen to raise polyclonal or monoclonal antibodies, and 4) as a therapeutic agent.

#### **B.** Nucleic Acid Molecules

The present invention further provides nucleic acid molecules that encode the protein having SEQ ID No.2 and the related proteins herein described, preferably in isolated form. As used herein, "nucleic acid" is defined as RNA or DNA that encodes a peptide as defined above, or is complementary to nucleic acid sequence encoding such peptides, or hybridizes to such nucleic acid and remains stably bound to it under

appropriate stringency conditions, or encodes a polypeptide sharing at least 75% sequence identity, preferably at least 80%, and more preferably at least 85%, with the peptide sequences. Specifically contemplated are genomic DNA, cDNA, mRNA and antisense molecules, as well as nucleic acids based on alternative backbone or including alternative bases whether derived from natural sources or synthesized. Such hybridizing or complementary nucleic acids, however, are defined further as being novel and nonobvious over any prior art nucleic acid including that which encodes, hybridizes under appropriate stringency conditions, or is complementary to nucleic acid encoding a protein according to the present invention.

"Stringent conditions" are those that (1) employ low ionic strength and high temperature for washing, for example, 0.015 M NaCl, 0.0015 M sodium titrate, 0.1% SDS at 50°C; or (2) employ during hybridization a denaturing agent such as formamide, for example, 50% (vol/vol) formamide with 0.1% bovine serum albumin, 0.1% Ficoll, 0.1% polyvinylpyrrolidone, 50 mM sodium phosphate buffer at pH 6.5
with 750 mM NaCl, 75 mM sodium citrate at 42°C. Another example is use of 50% formamide, 5X SSC (0.75 M NaCl, 0.075 M sodium citrate), 50 mM sodium phosphate (pH 6.8), 0.1% sodium pyrophosphate, 5X Denhardt's solution, sonicated salmon sperm DNA (50 μg/ml), 0.1% SDS, and 10% dextran sulfate at 42°C, with washes at 42°C in 0.2X SSC and 0.1% SDS. A skilled artisan can readily determine and vary the
stringency conditions appropriately to obtain a clear and detectable hybridization signal.

As used herein, a nucleic acid molecule is said to be "isolated" when the nucleic acid molecule is substantially separated from contaminant nucleic acid encoding other polypeptides from the source of nucleic acid.

The present invention further provides fragments of the encoding nucleic acid molecule. As used herein, a fragment of an encoding nucleic acid molecule refers to a small portion of the entire protein encoding sequence. The size of the fragment will be determined by the intended use. For example, if the fragment is chosen so as to encode an active portion of the protein, the fragment will need to be large enough to encode the

functional region(s) of the protein. If the fragment is to be used as a nucleic acid probe or PCR primer, then the fragment length is chosen so as to obtain a relatively small number of false positives during probing/priming.

Fragments of the encoding nucleic acid molecules of the present invention (i.e.,

5 synthetic oligonucleotides) that are used as probes or specific primers for the polymerase chain reaction (PCR), or to synthesize gene sequences encoding proteins of the invention can easily be synthesized by chemical techniques, for example, the phosphotriester method of Matteucci, et al., (J. Am. Chem. Soc. 103: 3185-3191, 1981) or using automated synthesis methods. In addition, larger DNA segments can readily be prepared by well known methods, such as synthesis of a group of oligonucleotides that define various modular segments of the gene, followed by ligation of oligonucleotides to build the complete modified gene.

The encoding nucleic acid molecules of the present invention may further be modified so as to contain a detectable label for diagnostic and probe purposes. A variety of such labels are known in the art and can readily be employed with the encoding molecules herein described. Suitable labels include, but are not limited to, biotin, radiolabeled nucleotides and the like. A skilled artisan can employ any of the art known labels to obtain a labeled encoding nucleic acid molecule.

Modifications to the primary structure itself by deletion, addition, or alteration of
the amino acids incorporated into the protein sequence during translation can be made
without destroying the activity of the protein. Such substitutions or other alterations result
in proteins having an amino acid sequence encoded by a nucleic acid falling within the
contemplated scope of the present invention.

#### 25 C. Isolation of Other Related Nucleic Acid Molecules

As described above, the identification of the human nucleic acid molecule having SEQ ID No.1 allows a skilled artisan to isolate nucleic acid molecules that encode other members of the  $p70\beta^{S6k}$  family in addition to the human sequence herein described. Further, the presently disclosed nucleic acid molecules allow a skilled artisan to isolate

nucleic acid molecules that encode other members of the  $p70\beta^{86k}$  family of proteins in addition to the disclosed protein having SEQ ID No.2.

Essentially, a skilled artisan can readily use the amino acid sequence of SEQ ID No.2 to generate antibody probes to screen expression libraries prepared from

5 appropriate cells. Typically, polyclonal antiserum from mammals such as rabbits immunized with the purified protein (as described below) or monoclonal antibodies can be used to probe a mammalian cDNA or genomic expression library, such as \( \lambda gtll \) library, to obtain the appropriate coding sequence for other members of the protein family. The cloned cDNA sequence can be expressed as a fusion protein, expressed directly using its own control sequences, or expressed by constructions using control sequences appropriate to the particular host used for expression of the enzyme.

Alternatively, a portion of the coding sequence herein described can be synthesized and used as a probe to retrieve DNA encoding a member of the protein family from any mammalian organism. Oligomers containing approximately 18-20 or 21 nucleotides

15 (encoding about a 6-7 amino acid stretch) are prepared and used to screen genomic DNA or cDNA libraries to obtain hybridization under stringent conditions or conditions of sufficient stringency to eliminate an undue level of false positives.

Additionally, pairs of oligonucleotide primers can be prepared for use in a polymerase chain reaction (PCR) to selectively clone an encoding nucleic acid molecule.

20 A PCR denature/anneal/extend cycle for using such PCR primers is well known in the art and can readily be adapted for use in isolating other encoding nucleic acid molecules.

#### D. rDNA molecules Containing a Nucleic Acid Molecule

The present invention further provides recombinant DNA molecules (rDNAs) that contain a coding sequence. As used herein, a rDNA molecule is a DNA molecule that has been subjected to molecular manipulation *in situ*. Methods for generating rDNA molecules are well known in the art, for example, see Sambrook *et al.*, (1989). In the preferred rDNA molecules, a coding DNA sequence is operably linked to expression control sequences and/or vector sequences.

The choice of vector and/or expression control sequences to which one of the protein family encoding sequences of the present invention is operably linked depends directly, as is well known in the art, on the functional properties desired, e.g., protein expression, and the host cell to be transformed. A vector contemplated by the present invention is at least capable of directing the replication or insertion into the host chromosome, and preferably also expression, of the structural gene included in the rDNA molecule.

Expression control elements that are used for regulating the expression of an operably linked protein encoding sequence are known in the art and include, but are not limited to, inducible promoters, constitutive promoters, secretion signals, and other regulatory elements. Preferably, the inducible promoter is readily controlled, such as being responsive to a nutrient in the host cell's medium.

In one embodiment, the vector containing a coding nucleic acid molecule will include a prokaryotic replicon, *i.e.*, a DNA sequence having the ability to direct autonomous replication and maintenance of the recombinant DNA molecule extrachromosomally in a prokaryotic host cell, such as a bacterial host cell, transformed therewith. Such replicons are well known in the art. In addition, vectors that include a prokaryotic replicon may also include a gene whose expression confers a detectable marker such as a drug resistance. Typical bacterial drug resistance genes are those that confer resistance to ampicillin or tetracycline.

Vectors that include a prokaryotic replicon can further include a prokaryotic or bacteriophage promoter capable of directing the expression (transcription and translation) of the coding gene sequences in a bacterial host cell, such as *E. coli*. A promoter is an expression control element formed by a DNA sequence that permits binding of RNA polymerase and transcription to occur. Promoter sequences compatible with bacterial hosts are typically provided in plasmid vectors containing convenient restriction sites for insertion of a DNA segment of the present invention. Typical of such vector plasmids are pUC8, pUC9, pBR322 and pBR329 available from Biorad Laboratories, (Richmond, CA), pPL and pKK223 available from Pharmacia, Piscataway, N.J.

Expression vectors compatible with eukaryotic cells, preferably those compatible with vertebrate cells, can also be used to form a rDNA molecules the contains a coding sequence. Eukaryotic cell expression vectors are well known in the art and are available from several commercial sources. Typically, such vectors are provided containing convenient restriction sites for insertion of the desired DNA segment. Typical of such vectors are pSVL and pKSV-10 (Pharmacia), pBPV-1/pML2d (International Biotechnologies, Inc.), pTDT1 (ATCC, #31255), the vector pCDM8 described herein, and the like eukaryotic expression vectors.

Eukaryotic cell expression vectors used to construct the rDNA molecules of the

10 present invention may further include a selectable marker that is effective in an eukaryotic cell, preferably a drug resistance selection marker. A preferred drug resistance marker is the gene whose expression results in neomycin resistance, *i.e.*, the neomycin phosphotransferase (*neo*) gene (Southern *et al.*, J. Mol. Anal. Genet 1: 327-341, 1982).

Alternatively, the selectable marker can be present on a separate plasmid, and the two vectors are introduced by co-transfection of the host cell, and selected by culturing in the appropriate drug for the selectable marker.

# E. Host Cells Containing an Exogenously Supplied Coding Nucleic Acid Molecule

The present invention further provides host cells transformed with a nucleic acid molecule that encodes a protein of the present invention. The host cell can be either prokaryotic or eukaryotic. Eukaryotic cells useful for expression of a protein of the invention are not limited, so long as the cell line is compatible with cell culture methods and compatible with the propagation of the expression vector and expression of the gene product. Preferred eukaryotic host cells include, but are not limited to, yeast, insect and mammalian cells, preferably vertebrate cells such as those from a mouse, rat, monkey or human cell line. Preferred eukaryotic host cells include Chinese hamster ovary (CHO) cells available from the ATCC as CCL61, NIH Swiss mouse embryo cells NIH/3T3 available from the ATCC as CRL 1658, baby hamster kidney cells (BHK), and the like eukaryotic

tissue culture cell lines.

Any prokaryotic host can be used to express a rDNA molecule encoding a protein of the invention. The preferred prokaryotic host is *E. coli*.

Transformation of appropriate cell hosts with a rDNA molecule of the present invention is accomplished by well known methods that typically depend on the type of vector used and host system employed. With regard to transformation of prokaryotic host cells, electroporation and salt treatment methods are typically employed, see, for example, Cohen et al., Proc. Natl. Acad. Sci. USA 69: 2110, 1972; and Maniatis et al., MOLECULAR CLONING, A LABORATORY MANUAL, Cold Spring Harbor Laboratory, Cold Spring Harbor,

10 NY (1982). With regard to transformation of vertebrate cells with vectors containing rDNAs, electroporation, cationic lipid or salt treatment methods are typically employed, see, for example, Graham *et al.*, Virol. 52: 456, 1973; Wigler *et al.*, Proc. Natl. Acad. Sci. USA 76: 1373-76, 1979.

Successfully transformed cells, i.e., cells that contain a rDNA molecule of the

15 present invention, can be identified by well known techniques including the selection for a
selectable marker. For example, cells resulting from the introduction of an rDNA of the
present invention can be cloned to produce single colonies. Cells from those colonies can
be harvested, lysed and their DNA content examined for the presence of the rDNA using a
method such as that described by Southern, <u>J. Mol. Biol.</u> 98:503, 1975, or Berent *et al.*,

20 <u>Biotech</u>. 3: 208, 1985 or the proteins produced from the cell assayed via an immunological method.

Recombinant p70β<sup>S6k</sup> DNA can also be utilized to analyze the function of coding and non-coding sequences. For example, the 5' untranslated region of the p70β<sup>S6k</sup> clone contains a GA repeat (nucleotides 1-66 of P70β<sup>S6k</sup>), that may modulate the initiation of translation of its mRNA. This sequence can be utilized in an affinity matrix system to purify proteins obtained from cell lysates that associate with the p70β<sup>S6k</sup> GA sequence. Synthetic oligonucleotides would be coupled to the beads and probed with the lysates, as is commonly known in the art. Associated proteins could then be separated using, for example, a two dimensional SDS-PAGE system. Proteins thus isolated could be further

identified using mass spectroscopy or protein sequencing.

# F. Production of Recombinant Proteins using a rDNA Molecule

The present invention further provides methods for producing a protein of the invention using nucleic acid molecules herein described. In general terms, the production of a recombinant form of a protein typically involves the following steps:

First, a nucleic acid molecule is obtained that encodes a protein of the invention, such as the nucleic acid molecule depicted in SEQ ID No. 1, or particularly for the p70β<sup>S6k</sup> nucleotides encoding the proline rich domain or the amino terminus of p70β<sup>S6k</sup>. The coding sequence is directly suitable for expression in any host, as it is not interrupted by introns. The sequence can be transfected into host cells such as eukaryotic cells or prokaryotic cells. Eukaryotic hosts include mammalian cells (e.g., HEK293 cells, CHO cells and PAE-PDGF-R cells) as well as insect cells such as Sf9 cells using recombinant baculovirus. Alternatively, fragments encoding only portion of p70β<sup>S6k</sup> can be expressed alone or in the form of a fusion protein. For example, the C-terminal fragment of p70β<sup>S6k</sup> containing the proline-rich domain, was expressed in bacteria as a GST- or His-tag fusion protein. These fusion proteins were then purified and used to generate polyclonal antibodies.

The nucleic acid molecule is then preferably placed in operable linkage with

20 suitable control sequences, as described above, to form an expression unit containing the
protein open reading frame. The expression unit is used to transform a suitable host and the
transformed host is cultured under conditions that allow the production of the recombinant
protein. Optionally the recombinant protein is isolated from the medium or from the cells;
recovery and purification of the protein may not be necessary in some instances where some

25 impurities may be tolerated.

Each of the foregoing steps can be done in a variety of ways. For example, the desired coding sequences may be obtained from genomic fragments and used directly in appropriate hosts. The construction of expression vectors that are operable in a variety of hosts is accomplished using appropriate replicons and control sequences, as set forth above.

The control sequences, expression vectors, and transformation methods are dependent on the type of host cell used to express the gene and were discussed in detail earlier. Suitable restriction sites can, if not normally available, be added to the ends of the coding sequence so as to provide an excisable gene to insert into these vectors. A skilled artisan can readily adapt any host/expression system known in the art for use with the nucleic acid molecules of the invention to produce recombinant protein.

## G. In Vitro Methods to Identify Binding Partners

Another embodiment of the present invention provides methods for use in isolating and identifying binding partners of proteins of the invention. In detail, a protein of the invention is mixed with a potential binding partner or an extract or fraction of a cell under conditions that allow the association of potential binding partners with the protein of the invention. After mixing, peptides, polypeptides, proteins or other molecules that have become associated with a protein of the invention are separated from the mixture. The binding partner that bound to the protein of the invention can then be removed and further analyzed. To identify and isolate a binding partner, the entire protein, for instance the entire disclosed protein of SEQ ID No.2 can be used. Alternatively, a fragment of the protein can be used.

As used herein, a cellular extract refers to a preparation or fraction which is 20 made from a lysed or disrupted cell.

A variety of methods can be used to obtain cell extracts. Cells can be disrupted using either physical or chemical disruption methods. Examples of physical disruption methods include, but are not limited to, sonication and mechanical shearing. Examples of chemical lysis methods include, but are not limited to, detergent lysis and enzyme lysis. A skilled artisan can readily adapt methods for preparing cellular extracts in order to obtain extracts for use in the present methods.

Once an extract of a cell is prepared, the extract is mixed with the protein of the invention under conditions in which association of the protein with the binding partner can occur. A variety of conditions can be used, the most preferred being conditions that

20

WO 00/08173 PCT/US99/17595

closely resemble conditions found in the cytoplasm of a human cell. Features such as osmolarity, pH, temperature, and the concentration of cellular extract used, can be varied to optimize the association of the protein with the binding partner.

After mixing under appropriate conditions, the bound complex is separated from the mixture. A variety of techniques can be utilized to separate the mixture. For example, antibodies specific to a protein of the invention can be used to immunoprecipitate the binding partner complex. Alternatively, standard chemical separation techniques such as chromatography and density/sediment centrifugation can be used.

After removal of non-associated cellular constituents found in the extract, the binding partner can be dissociated from the complex using conventional methods. For example, dissociation can be accomplished by altering the salt concentration or pH of the mixture.

To aid in separating associated binding partner pairs from the mixed extract, the protein of the invention can be immobilized on a solid support. For example, the protein can be attached to a nitrocellulose matrix or acrylic beads. Attachment of the protein to a solid support aids in separating peptide/binding partner pairs from other constituents found in the extract. The identified binding partners can be either a single protein or a complex made up of two or more proteins.

Alternatively, the nucleic acid molecules of the invention can be used in a yeast two-hybrid system. The yeast two-hybrid system has been used to identify other protein partner pairs and can readily be adapted to employ the nucleic acid molecules herein described.

One preferred *in vitro* binding assay for p70β<sup>S6k</sup> would comprise a mixture of a polypeptide comprising at least the kinase domain of p70β<sup>S6k</sup> and one or more candidate binding targets or substrates. After incubating the mixture under appropriate conditions, one would determine whether p70β<sup>S6k</sup> or a polypeptide fragment thereof containing the kinase region either bound with the candidate substrate or phosphorylated the candidate substrate. For cell-free binding assays, one of the

components usually comprises or is coupled to a label. The label may provide for direct detection, such as radioactivity, luminescence, optical or electron density, etc., or indirect detection such as an epitope tag, an enzyme, etc. A variety of methods may be employed to detect the label depending on the nature of the label and other assay components. For example, the label may be detected bound to the solid substrate or a portion of the bound complex containing the label may be separated from the solid substrate, and the label thereafter detected.

# H. Methods to Identify Agents that Modulate the Expression a Nucleic Acid Encoding the S6 Kinase Protein.

Another embodiment of the present invention provides methods for identifying agents that modulate the expression of a nucleic acid encoding a protein of the invention such as a protein having the amino acid sequence of SEQ ID No.2. Such assays may utilize any available means of monitoring for changes in the expression level of the nucleic acids of the invention. As used herein, an agent is said to modulate the expression of a nucleic acid of the invention, for instance a nucleic acid encoding the protein having the sequence of SEQ ID No.2, if it is capable of up- or down-regulating expression of the nucleic acid in a cell.

In one assay format, cell lines that contain reporter gene fusions between the open reading frame defined by p70β<sup>S6k</sup> nucleotides 77-1,564 or 116-1,564 of SEQ ID No.1 and any assayable fusion partner may be prepared. Numerous assayable fusion partners are known and readily available including the firefly luciferase gene and the gene encoding chloramphenicol acetyltransferase (Alam *et al.*, 1990 <u>Anal. Biochem.</u> 188: 245-254). Cell lines containing the reporter gene fusions are then exposed to the agent to be tested under appropriate conditions and time. Differential expression of the reporter gene between samples exposed to the agent and control samples identifies agents which modulate the expression of a nucleic acid encoding the protein having the sequence of SEQ ID No.2.

Additional assay formats may be used to monitor the ability of the agent to

modulate the expression of a nucleic acid encoding a protein of the invention such as the protein having SEQ ID No.2. For instance, mRNA expression may be monitored directly by hybridization to the nucleic acids of the invention. Cell lines are exposed to the agent to be tested under appropriate conditions and time and total RNA or mRNA is isolated by standard procedures such those disclosed in Sambrook *et al.* (Molecular Cloning: A Laboratory Manual, 2nd Ed. Cold Spring Harbor Laboratory Press, 1989).

Probes to detect differences in RNA expression levels between cells exposed to the agent and control cells may be prepared from the nucleic acids of the invention. It is preferable, but not necessary, to design probes which hybridize only with target nucleic acids under conditions of high stringency. Only highly complementary nucleic acid hybrids form under conditions of high stringency. Accordingly, the stringency of the assay conditions determines the amount of complementarity which should exist between two nucleic acid strands in order to form a hybrid. Stringency should be chosen to maximize the difference in stability between the probe:target hybrid and potential probe:non-target hybrids.

Probes may be designed from the nucleic acids of the invention through methods known in the art. For instance, the G+C content of the probe and the probe length can affect probe binding to its target sequence. Methods to optimize probe specificity are commonly available in Sambrook et al. (1989) or Ausubel et al. (CURRENT PROTOCOLS IN MOLECULAR BIOLOGY, Greene Publishing Co., NY, 1995).

Hybridization conditions are modified using known methods, such as those described by Sambrook et al. (1989) and Ausubel et al. (1995) as required for each probe. Hybridization of total cellular RNA or RNA enriched for polyA RNA can be accomplished in any available format. For instance, total cellular RNA or RNA enriched for polyA RNA can be affixed to a solid support and the solid support exposed to at least one probe comprising at least one, or part of one of the sequences of the invention under conditions in which the probe will specifically hybridize.

Alternatively, nucleic acid fragments comprising at least one, or part of one of the

sequences of the invention can be affixed to a solid support, such as a porous glass wafer. The glass wafer can then be exposed to total cellular RNA or polyA RNA from a sample under conditions in which the affixed sequences will specifically hybridize. Such glass wafers and hybridization methods are widely available, for example, those disclosed by Beattie (WO 95/11755). By examining for the ability of a given probe to specifically hybridize to an RNA sample from an untreated cell population and from a cell population exposed to the agent, agents which up or down regulate the expression of a nucleic acid encoding the protein having the sequence of SEQ ID No.2 are identified.

10

# I. Cell-Based Methods to Identify Binding Partners and Agents that Modulate at Least One Activity of the S6 Kinase Protein and Related Antibodies.

Another embodiment of the present invention provides methods for identifying agents that modulate at least one activity of a protein of the invention such as the

15 protein having the amino acid sequence of SEQ ID No.2. Such methods or assays may utilize any means of monitoring or detecting the desired activity.

In one format, the relative amounts of a protein of the invention between a cell population that has been exposed to the agent to be tested compared to an un-exposed control cell population may be assayed. In this format, probes such as specific 20 antibodies are used to monitor the differential expression of the protein in the different cell populations. Cell lines or populations are exposed to the agent to be tested under appropriate conditions and time. Cellular lysates may be prepared from the exposed cell line or population and a control, unexposed cell line or population. The cellular lysates are then analyzed with the probe.

For example, N- and C- terminal fragments of  $p70\beta^{S6k}$  can be expressed in bacteria and used to search for proteins which bind to these fragments. Fusion proteins, such as His-tag or GST fusion to the N- or C-terminal regions of  $p70\beta^{S6k}$  can be prepared for use as a  $p70\beta^{S6k}$  fragment substrate. These fusion proteins can be coupled to Talon or Glutathione-Sepharose beads and then probed with cell lysates. Prior to

lysis, the cells may be treated with rapamycin or other drugs which may modulate p70β<sup>S6k</sup> or proteins that interact with p70β<sup>S6k</sup>. Lysate proteins binding to the fusion proteins can be resolved by SDS-PAGE, isolated and identified by protein sequencing or mass spectroscopy, as is known in the art. It is likely that signaling molecules containing one or more SH3 domains may bind directly to the C-terminal region of p70β<sup>S6k</sup>. The N-terminal domain may have a p70β<sup>S6k</sup>-specific phosphatase as a binding partner.

Antibody probes are prepared by immunizing suitable mammalian hosts in appropriate immunization protocols using the peptides, polypeptides or proteins of the invention, such as p70β<sup>56k</sup>, variants and isolated binding partners, if they are of sufficient length, or, if desired, or if required to enhance immunogenicity, conjugated to suitable carriers. Methods for preparing immunogenic conjugates with carriers such as bovine serum albumin (BSA), keyhole limpet hemocyanin (KLH), or other carrier proteins are well known in the art. In some circumstances, direct conjugation using, for example, carbodiimide reagents may be effective; in other instances linking reagents such as those supplied by Pierce Chemical Co., Rockford, IL, may be desirable to provide accessibility to the hapten. The hapten peptides can be extended at either the amino or carboxy terminus with a Cys residue or interspersed with cysteine residues, for example, to facilitate linking to a carrier. Administration of the immunogens is conducted generally by injection over a suitable time period and with use of suitable adjuvants, as is generally understood in the art. During the immunization schedule, titers of antibodies are taken to determine adequacy of antibody formation.

Anti-peptide antibodies can be generated using synthetic peptides corresponding to, for example, the carboxy terminal 15 amino acids p70β<sup>56k</sup>. Synthetic peptides can be as small as 1-3 amino acids in length, but are preferably at least 4 or more amino acid residues long. The peptides are coupled to KLH using standard methods and can be immunized into animals such as rabbits. Polyclonal anti-p70β<sup>56k</sup> peptide antibodies can then be purified, for example using Actigel beads containing the covalently bound peptide.

While the polyclonal antisera produced in this way may be satisfactory for some applications, for pharmaceutical compositions, use of monoclonal preparations is preferred. Immortalized cell lines which secrete the desired monoclonal antibodies may be prepared using the standard method of Kohler and Milstein or modifications which effect immortalization of lymphocytes or spleen cells, as is generally known. The immortalized cell lines secreting the desired antibodies are screened by immunoassay in which the antigen is the peptide hapten. polypeptide or protein. When the appropriate immortalized cell culture secreting the desired antibody is identified, the cells can be cultured either *in vitro* or by production in ascites fluid. Of particular interest, are

The desired monoclonal antibodies are then recovered from the culture supernatant or from the ascites supernatant. Fragments of the monoclonals or the polyclonal antisera which contain the immunologically significant portion can be used as antagonists, as well as the intact antibodies. Use of immunologically reactive 15 fragments, such as Fav, Fv, Fab, Fab', or F(ab'), fragments is often preferable, especially in a therapeutic context, as these fragments are generally less immunogenic than the whole immunoglobulin. Antibodies may preferably also be human, humanized or chimeric variants of the foregoing. Such antibodies can be less immunogenic when administered to a subject. Methods of producing humanized or chimeric antibodies are 20 well known in the art. The antibodies contemplated also include different isotypes and isotype subclasses (e.g., IgG<sub>1</sub>, IgG<sub>2</sub>, IgM, to name a few). These antibodies can be prepared by raising them in vertebrates, in hybridoma cell lines or other cell lines, or by recombinant means. For references on how to prepare these antibodies, see E. Harlow and D. Lane, ANTIBODIES: A LABORATORY MANUAL (Cold Spring Harbor 25 Press, Cold Spring Harbor, NY, 1988); Kohler and Milstein, (1976) E. J. Immunol. 6:511; Queen et al. U.S. Patent NO. 5,585,089; and Riechmann et al., Nature 332:323 (1988).

The antibodies or fragments may also be produced, using current technology, by recombinant means. Regions that bind specifically to the desired regions of receptor

can also be produced in the context of chimeras with multiple species origin.

In an alternative format, a specific activity of a protein of the invention may be assayed, such as the ability of the protein to phosphorylate a substrate such as polypeptides of the S6 protein. For example, p70β<sup>s6k</sup> has been demonstrated to

5 phosphorylate the S6 protein and a synthetic peptide, RRLSSLRASTSKSESSQK (SEQ ID No. 8). The sequence comprising the synthetic peptide is located in the C-terminus of the S6 protein and is known to contain the five phosphorylation sites targeted by p70α<sup>s6k</sup>. Cell lines or populations are exposed under appropriate conditions to the agent to be tested. Agents which modulate the kinase activity of the protein of the invention are identified by assaying the kinase activity of the protein from the exposed cell line or population and a control, unexposed cell line or population, thereby identifying agents which modulate the kinase activity of the protein. Polypeptides of the S6 protein, such as the above examples, are useful positive controls in identifying additional p70β<sup>s6k</sup> substrates.

15 Kinase assays to measure the ability of the agent to modulate the kinase activity of a protein of the invention are widely available such as the assays disclosed by Mishima et al. (1996) J. Biochem. 119: 906-913) and Michnoff et al. (1986) J. Biol. Chem. 261: 8320-8326. Alternative assay formats include actin-myosin motility assays such as those disclosed by Kohama et al. (1996) TIPS 17: 284-287 or Warrick et al. 20 (1987) Ann. Rev. Cell. Biol. 3: 379-421.

Agents that are assayed in the above method can be randomly selected or rationally selected or designed. As used herein, an agent is said to be randomly selected when the agent is chosen randomly without considering the specific sequences involved in the association of the a protein of the invention alone or with its associated substrates, binding partners, etc. An example of randomly selected agents is the use a chemical library or a peptide combinatorial library, or a growth broth of an organism.

As used herein, an agent is said to be rationally selected or designed when the agent is chosen on a non-random basis which takes into account the sequence of the target site and/or its conformation in connection with the agent's action. As described

in the Examples, there are proposed binding sites for ATP/GTP and calmodulin as well as cAMP/cGMP kinase sites, TyrP sites and Ser/Thr kinase (catalytic) sites in the protein having SEQ ID No.2. Agents can be rationally selected or rationally designed by utilizing the peptide sequences that make up these sites. For example, a rationally selected peptide agent can be a peptide whose amino acid sequence is identical to the ATP or calmodulin binding sites or domains.

The agents of the present invention can be, as examples, peptides, small molecules, vitamin derivatives, as well as carbohydrates. A skilled artisan can readily recognize that there is no limit as to the structural nature of the agents of the present invention.

The peptide agents of the invention can be prepared using standard solid phase (or solution phase) peptide synthesis methods, as is known in the art. In addition, the DNA encoding these peptides may be synthesized using commercially available oligonucleotide synthesis instrumentation and produced recombinantly using standard recombinant production systems. The production using solid phase peptide synthesis is necessitated if non-gene-encoded amino acids are to be included.

Another class of agents of the present invention are antibodies immunoreactive with critical positions of proteins of the invention. Antibody agents are obtained by immunization of suitable mammalian subjects with peptides, containing as antigenic regions, those portions of the protein intended to be targeted by the antibodies.

# J. Uses for Agents that Modulate at Least One Activity of the S6 Kinase Protein.

As provided in the Examples, the proteins and nucleic acids of the invention,

such as the protein having the amino acid sequence of SEQ ID No.2, are involved in
ribosomal function. Agents that modulate or down-regulate the expression of the
protein or agents such as agonists or antagonists of at least one activity of the protein
may be used to modulate biological and pathologic processes associated with the
protein's function and activity.

As used herein, a subject can be any mammal, so long as the mammal is in need of modulation of a pathological or biological process mediated by a protein of the invention. The term "mammal" is meant an individual belonging to the class Mammalia. The invention is particularly useful in the treatment of human subjects.

As used herein, a biological or pathological process mediated by a protein of the invention may include binding of substrates such as ATP, GTP or calmodulin or phosphorylation of a substrate, such as the S6 protein.

Pathological processes refer to a category of biological processes which produce a deleterious effect. For example, expression or up-regulation of expression of a protein of the invention may be associated with certain diseases. As used herein, an agent is said to modulate a pathological process when the agent reduces the degree or severity of the process. For instance, a disease may be prevented or disease progression modulated by the administration of agents which reduce or modulate in some way the expression or at least one activity of a protein of the invention.

The agents of the present invention can be provided alone, or in combination with other agents that modulate a particular pathological process. As used herein, two agents are said to be administered in combination when the two agents are administered simultaneously or are administered independently in a fashion such that the agents will act at the same time.

The agents of the present invention can be administered via parenteral, subcutaneous, intravenous, intramuscular, intraperitoneal, transdermal, or buccal routes. Alternatively, or concurrently, administration may be by the oral route. The dosage administered will be dependent upon the age, health, and weight of the recipient, kind of concurrent treatment, if any, frequency of treatment, and the nature of the effect desired.

The present invention further provides compositions containing one or more agents which modulate expression or at least one activity of a protein of the invention. While individual needs vary, determination of optimal ranges of effective amounts of each component is within the skill of the art. Typical dosages comprise about 0.1 to

100 μg/kg body weight. The preferred dosages comprise about 0.1 to 10 μg/kg body weight. The most preferred dosages comprise about 0.1 to 1 μg/kg body weight. In tissue culture, optimal dosage ranges for drugs such as wortmannin and rapamycin range from about 500 pM to about 1000 nM. Less optimum ranges include about 10 pM to about 10 mg.

In addition to the pharmacologically active agent, the compositions of the present invention may contain suitable pharmaceutically acceptable carriers comprising excipients and auxiliaries which facilitate processing of the active compounds into preparations which can be used pharmaceutically for delivery to the site of action.

- 10 Suitable formulations for parenteral administration include aqueous solutions of the active compounds in water-soluble form, for example, water-soluble salts. In addition, suspensions of the active compounds as appropriate oily injection suspensions may be administered. Suitable lipophilic solvents or vehicles include fatty oils, for example, sesame oil, or synthetic fatty acid esters, for example, ethyl oleate or triglycerides.
- 15 Aqueous injection suspensions may contain substances which increase the viscosity of the suspension include, for example, sodium carboxymethyl cellulose, sorbitol, and/or dextran. Optionally, the suspension may also contain stabilizers. Liposomes can also be used to encapsulate the agent for delivery into the cell.

The pharmaceutical formulation for systemic administration according to the invention may be formulated for enteral, parenteral or topical administration. Indeed, all three types of formulations may be used simultaneously to achieve systemic administration of the active ingredient.

Suitable formulations for oral administration include hard or soft gelatin capsules, pills, tablets, including coated tablets, elixirs, suspensions, syrups or inhalations and controlled release forms thereof.

In practicing the methods of this invention, the compounds of this invention may be used alone or in combination, or in combination with other therapeutic or diagnostic agents. In certain preferred embodiments, the compounds of this invention may be coadministered along with other compounds typically prescribed for these

conditions according to generally accepted medical practice. The compounds of this invention can be utilized *in vivo*, ordinarily in mammals, such as humans, sheep, horses, cattle, pigs, dogs, cats, rats and mice, or *in vitro*.

Without further description, it is believed that one of ordinary skill in the art

5 can, using the preceding description and the following illustrative examples, make and
utilize the compounds of the present invention and practice the claimed methods. The
following working examples therefore, specifically point out preferred embodiments of
the present invention, and are not to be construed as limiting in any way the remainder
of the disclosure.

10

### **EXAMPLES**

#### **EXAMPLE 1**

## Amino Acid Sequence of $p70\beta^{S6k}$ and comparison with $p70\alpha^{S6k}$

Materials and Methods. Restriction enzymes and DNA modification enzymes were obtained from standard commercial sources and used according to manufacturer's recommendations. Oligonucleotides which were used for sequencing of p70β<sup>S6k</sup> and various PCR fragments were synthesized by Genosys or Japan Bioservice, Inc. The pcDNA1 and pcDNA3 mammalian expression vectors were from Invitrogen. The pGEX-4T vector, glutathione-Sepharose-4B and HiTrapQ columns were purchased from Pharmacia. cDNA of rat p70α-I was a gift from Dr. Joseph Avruch (Diabetes Unit, Massachusetts General Hospital). Rapamycin and PDGF BB were purchased form Calbiochem. Wortmannin was purchased from Sigma.

Cell cultures and Antibodies. A porcine aortic endothelial cell line (PAE-PDGF-R), stably expressing the human PDGF-β receptor, was maintained in HAM's F12 medium containing 10% fetal calf serum (FCS). CHO cells stably overexpressing human insulin receptors (CHO-IR cells) and HEK293 cells were maintained and cultured as described earlier (Hara et al., 1998 J. Biol. Chem. 273: 14484-14494) in HAM's F12 medium or Dulbecco's modified Eagles minimal essential medium (DMEM) supplemented with 10% FCS, respectively. Anti-FLAG monoclonal M2

antibody was purchased from Eastman Kodak Corp. Anti-phosphopeptide antibodies against proline-directed site Ser434 of p70α-I were purchased from New England Biolabs. Polyclonal antibodies raised against the C-terminal 104 amino acids fragment of p70α<sup>S6k</sup> were from Dr. Joseph Avruch. A GST fusion protein containing amino acids 443-495 of p70β<sup>S6k</sup> (p70βC Ab) was used to raise polyclonal antibodies specific for p70β<sup>S6k</sup>. Immunoreactive sera were affinity-purified on an Affigel matrix containing the GST/p70β<sup>S6k</sup>-terminal fusion protein.

Fractionation of cell extracts. HEK293 cells were starved in DMEM medium for 16 h and then treated with 15% FCS for 10 min or 200 nM rapamycin for 30 min.

10 After treatment, cells were lysed in ice-cold buffer A (20mM Tris/HCl pH 7.5, 20 mM NaCl, 1 mM EDTA, 5 mM EGTA, 20 mM β-glycerophosphate, 1 mM-DTT, 1 mM PMSF, 2 mg/ml aprotinin, 10 mg/ml leupeptin) and the lysates centrifuged at 4°C for 20 min at 10,000xg. Supernatants were filtered through a 0.45 μM filter and then loaded onto a HighTrapQ Sepharose column (1.0 ml column volume) equilibrated in Buffer A. The column was washed extensively in buffer A and bound proteins eluted with a linear gradient of NaCl (20 - 500 mM). Aliquots of eluted proteins were subjected to SDS- PAGE and immunoblotted with anti-phosphopeptide antibodies directed against proline-directed site Ser-434 of p70α<sup>S6k</sup> or anti-peptide antibodies against the carboxyl terminal end of p70α<sup>S6k</sup>.

Construction and screening of a HEK293 Uni-ZAP library and DNA sequencing analysis. Total RNA was isolated from HEK293 cells as described (Hara et al., 1998; Chomczynski et al., 1987 Analytical Biochem. 162: 156-159), and poly(A)+ mRNA was selected by using Dynabeads mRNA purification kit (Dynal). An oligo(dT)-primed library was constructed in UNI-ZAP XR vector from 5 mg of
 HEK293 mRNA, using the Uni-ZAP cDNA synthesis kit (Stratagene). Packaging into phages was carried out by using Gigapack III Gold Packaging extracts (Stratagene). The cDNA encoding full length p70β<sup>S6k</sup> kinase was isolated by screening 1x10<sup>6</sup> primary phages from HEK293 Uni-ZAP library with a <sup>32</sup>P-labeled 0.65 Kb EcoRI/NotI fragment derived from the EST clone GenBank Accession No. AA410355 (Hillier et al.,

published on GenBank, 1997). Positive clones were confirmed, isolated in second-round screening and rescued as Bluescript plasmids by in vivo excision (Stratagene).
PCR amplification and restriction mapping were used for primary characterization of isolated clones. Sequencing analysis of selected clones was performed on an Applied
Biosystem 373A DNA automatic sequencer (PE Applied Biosystems).

**Results.** The p $70\alpha^{S6k}$  is activated by multiple phosphorylation within the pseudosubstrate and catalytic domains in response to extracellular stimuli, including serum, growth factors and hormones. Phosphospecific antibodies directed against phosphorylated sites of p $70\alpha^{S6k}$  have been recently developed: Phospho-p $70\alpha^{S6k}$ 10 (Ser434) and Phospho-p70 $\alpha$ <sup>S6k</sup> (Thr444/Ser447). Both antibodies were shown to recognize specifically phosphorylated forms of p70 $\alpha$ <sup>S6k</sup>, and this recognition was found to be sensitive to rapamycin. To compare the phosphorylation state and chromatographic behavior of p70α<sup>S6k</sup> from cells stimulated with serum and treated with or without rapamycin, HEK293 cells were starved in DMEM medium for 16 h and then 15 stimulated with 15% serum for 10 min prior treatment with or without 200 nM of rapamycin for 30 min. Cell extracts were fractionated using HighTrapQ Sepharose columns. Proteins were resolved on SDS-PAGE and immunoblotted with antiphosphopeptide antibodies Ser434 and S444/T447 or antibodies specific for p70α<sup>56k</sup>. In total lysates of serum stimulated HEK293 cells, this antibody recognizes specifically 20 phosphorylated versions of p $70\alpha^{56k}$  isoforms (p70 and p85). However, when cell lysates were fractionated and separated on SDS-PAGE, several additional bands appeared on the immunoblot together with the p70 and p85 isoforms of p70 $\alpha$ <sup>S6k</sup>. including p190, p110, p90 and p60 (not shown). It is important to note that the recognition of these proteins by phosphospecific S434 antibodies was sensitive to 25 rapamycin, indicating the specificity for the phosphorylated epitope. As expected, the anti-peptide antibodies specific for the p70αS6k recognized 85-kDa and 70-kDa bands, which correspond to  $p70\alpha$ -I and  $p70\alpha$ -II, respectively. S434 is located in the

autoinhibitory region of the p70 $\alpha^{S6k}$ , which is highly conserved among different species of p70 $\alpha^{S6k}$ , including Drosophila (Stewart *et al.*, 1996 <u>Proc. Natl Acad. Sci. USA</u> 93:

10791-10796; Watson *et al.*, 1996 <u>Proc. Natl Acad. Sci. USA</u> 93: 13694-13698). As phosphorylation of the S434 site is sensitive to rapamycin, it is possible to speculate that p190, p110, p90 and/or p60 may represent novel rapamycin-sensitive p $70\alpha^{S6k}$ -related kinases.

Molecular cloning of novel  $p70a^{S6k}$ . Peptide sequences which were used for 5 raising anti-phosphopeptide antibodies S434 of p $70\alpha$ -I were taken to search the expressed sequence tag (EST) databases. This search generated hundreds of EST clones that showed high degree of homology to the query sequence. Extensive analysis of these clones allowed us to isolate several clones which were highly homologous to 10 the 434 peptide, but did not match to cDNA clones from EMBL or Swissprot databases. Further characterization of these sequences indicated that two nearly identical clones (GenBank Accession Nos. AA284234 and AA410355) exhibited strong homology to the kinase extension domain of the protein kinase A (PKA) family of serine/threonine (S/T) kinases. Additionally, the homology in the kinase extension domain extended 15 into the putative autoinhibitory domain, which is unique for the  $p70\alpha^{S6k}$  (less than 75% identity between  $p70\alpha^{SGL}$  and the unknown potential S6 kinase). However, the homology with  $p70\alpha^{S6k}$  dropped significantly downstream of the kinase extension and autoinhibitory domains, suggesting that these clones encoded a novel kinase of this family. Based on these data, we decided to further characterize these clones. Both EST 20 clones were obtained from the UK HGMP Resource Center. Restriction mapping indicated that the GenBank Accession Nos. AA284234 and AA410355 clones contain short inserts of 0.6 kB and 0.65 kB respectively. Sequence analysis showed that these clones are identical to each other in an overlapping region and may encode a partial open reading frame (ORF), which shows very strong homology to the kinase extension 25 and autoinhibitory domains of the  $p70\alpha^{S6k}$ . These ESTs did not contain a full gene nor was there a protein coding sequence previously identified in these ESTs. Furthermore, four of the five proline-directed Ser/Thr phosphorylation sites located in an autoinhibitory pseudo-substrate domain of  $p70\alpha^{S6k}$  were conserved in the clones of p70β<sup>s6k</sup>. Immediately after the autoinhibitory pseudo-substrate domain, the homology

WO 00/08173 PCT/US99/17595

between  $p70\alpha^{S6k}$  and  $p70\beta^{S6k}$  was very low (12% identity). Taking in account these findings, we proceeded to clone the full length cDNA clone encoding this potentially novel kinase.

Since several rapamycin-sensitive bands were found in the HEK293 cells with

5 the use of anti-Ser434 phosphospecific antibodies, a library from this cell line was
created. We screened 10<sup>6</sup> primary clones from the Uni-Zap/HEK293 library with a full
length insert from EST clone AA410355 and isolated 12 positive clones. Sequence
analysis of rescued plasmids allowed us to identify one clone, which contained an open
reading frame of 495 amino acids (Figure 2A). The C-terminus of this clone was found

10 to be identical to the sequence of the EST clone AA410355, which was used for
screening.

By analogy to p70α<sup>S6k</sup>, the novel cDNA, encoding p70β<sup>S6k</sup>, could potentially encode two isoforms as a result of alternative start codons. If this is the case, the shorter isoform may utilize an ATG codon which is 13 amino acids (aa) downstream of the first methionine and may encode a protein of 482 amino acids. Two potential isoforms were termed p70β-I (495 aa long) and p70β-II (482 aa long). The presence of additional 13 aa at the N-terminus of p70β-I isoform may determine its subcellular localization in the nucleus due to the presence of a putative nuclear localization sequence (RGRRARG, amino acid numbers 3-9 of SEQ ID No. 2). The overall structure of p70β<sup>S6k</sup> is similar to that of p70α<sup>S6k</sup>. p70α<sup>S6k</sup> and p70β<sup>S6k</sup> share 70% identity and 85% similarity on protein level. The p70β<sup>S6k</sup> kinase consists of the aminoterminal non-catalytic region, a catalytic domain, a kinase extension and a carboxylterminal non-catalytic tail, whose amino acid identity corresponds to domains of p70α<sup>S6k</sup> is 40%, 83%, 80%, and 47%, respectively (Figure 2B). The strong argument that this clone encodes a novel p70 S6 kinase is the presence of the autoinhibitory pseudosubstrate domain, which is not present in any other known kinases.

 $p70\alpha^{S6k}$  undergoes a multi-site phosphorylation in response to stimulation by insulin or mitogens. Such multiple phosphorylation sites are also well conserved in  $p70\beta^{S6k}$  (Figure 2B). It also contains 3 sets of phosphorylation sites, similar to  $p70\alpha^{S6k}$ :

(i) a set of Ser/Thr-Pro motifs clustered in an autoinhibitory pseudosubstrate domain (Ser423, Ser430, Ser436, Ser441 in p70β<sup>s6k</sup> correspond to Ser 434, 441, and 447, Ser 452 in p70α<sup>s6k</sup>; (ii) a second set includes Ser383 and Thr401 which is located in the kinase extension domain and corresponds to Ser394 and Thr412 in p70α<sup>s6k</sup>; (iii) a third set consists of Thr251 which resides in the activation T-loop of kinase domain and corresponds to Thr252 in p70α<sup>s6k</sup>. The greatest difference between the p70α<sup>s6k</sup> and the p70β<sup>s6k</sup> sequences are in the amino-terminal non-catalytic region (40% identity and 60% similarity) and the carboxyl-terminal non-catalytic tail (47% identity and 66% similarity). p70β<sup>s6k</sup> also contains proline-rich sequences at the C-terminus, that may mediate the interaction with SH3-domain-containing molecules.

## **EXAMPLE 2**

## Tissue Specific Expression of p70β<sup>S6k</sup>

Materials and Methods. Northern blot analysis was performed using
 commercial nylon membranes pre-bound with 2 μg of gel-separated poly(A)+ RNA

- samples obtained from various human tissues or tumor cell lines from Clontech. The following probes were used for the detection of p $70\alpha^{86k}$  and p $70\beta^{86k}$  messages: (i) a 476-base pair (bp) *HindIII* fragment spanning 56 bp of 3' end coding region and 420 bp of 3' non-coding region of the human p $70\alpha^{86k}$  (EST clone, AA425599), (ii) a 650-bp
- fragment spanning 518 bp upstream of the stop codon and about 130 bp of non-coding region of the human p70 $\beta^{s6k}$  (EST clone, AA410355). Human  $\beta$ -actin cDNA probe was used as a negative control (Clontech). These probes were labeled by Multiprime DNA labeling system (Amersham) and separated from unincorporated [ $\gamma^{32}$ P]dCTP by Nuctrap push columns (Stratagene). Northern blots were pre-hybridized with
- 25 ExpressHyb solution and hybridized with labeled probes according to manufacturer's recommendations. After extensive washing with 2X SSC, 0.05% sodium dodecyl sulfate (SDS) at room temperature, and twice with 0.1X SSC, 0.1% SDS at 50°C, the localization of bound probes on membranes was identified by autoradiography or with the use of the PhosphoImager.

Results. In order to compare expression patterns of p70α<sup>S6k</sup> and p70β<sup>S6k</sup> in human tissues and cell lines, 3' prime coding and non-coding regions, which exhibit low level of homology between both the α and β S6 kinases, were used as probes. Northern blot analysis using poly(A)+ RNA isolated from human tissues revealed a
5 single 2.2 kb transcript for p70β<sup>S6k</sup>, while p70α<sup>S6k</sup> probe specifically hybridized to 3.4 kb and 7.4 kb transcripts (Figure 3A). The expression pattern of p70α<sup>S6k</sup> and p70β<sup>S6k</sup> transcripts is remarkably similar, showing ubiquitous expression in all tissues. Highest expression levels were found in spleen, skeletal muscle and peripheral blood leukocytes, whereas brain, lung and kidney showed the lowest expression of transcripts for both S6 kinases. The only significant difference on the level of mRNA expression between p70α<sup>S6k</sup> and p70β<sup>S6k</sup> was found in liver. The expression of p70β<sup>S6k</sup> mRNA in liver is 2-3 times higher than that of p70α<sup>S6k</sup>. Liver possesses a high concentration of p70α<sup>S6k</sup> and was originally used by several groups to purify p70α<sup>S6k</sup> for biochemical studies and protein sequencing analysis (Banerjee *et al.*, 1990 Proc. Natl Acad. Sci. USA 87: 7365-7369).
15 USA 87: 8550-8554; Kozma *et al.*, 1990 Proc. Natl Acad. Sci. USA 87: 7365-7369).

We also analyzed the expression of p70β<sup>sek</sup> mRNA in tumor cell lines using the same probe as for the analysis of tissue distribution. A single transcript of the same size as in human tissues, 2.2 kb, was found to be highly expressed in HeLa and K562 cells, but was barely detectable in HL-60, MOLT-4 and melanoma G361 cell lines 20 (Figure 3B).

## **EXAMPLE 3**

Phosphorylation of the ribosomal protein S6 and its C-terminal synthetic peptide by  $p70\alpha^{S6k}$  and  $p70\beta^{S6k}$ 

Materials and Methods. Expression of GST/p70β<sup>S6k</sup> fusion protein in bacteria. A PCR-based strategy was used to make a bacterial expression plasmid for GST/p70β<sup>S6k</sup> fusion protein. A cDNA fragment encoding 443-495 amino acids of p70β<sup>S6k</sup> was amplified by PCR and cloned into the pGEX-4T expression vector (Pharmacia). This construct was transformed into E. coli XL1-Blue competent cells

(Stratagene) and the expression of the GST/p70β<sup>S6k</sup> fusion protein was induced by isopropyl β-D-thiogalactopyranoside (IPTG). The GST/p70β<sup>S6k</sup> fusion protein was purified by using glutathione-Sepharose-4B beads according to manufacturer's recommendation (Pharmacia). After SDS-PAGE analysis, affinity purified fusion proteins were dialyzed against 20 mM (Tris pH 7.4), 150 mM NaCl, 50% Glycerol and stored at -20°C. This preparation of the GST/p70β<sup>S6k</sup> C-terminal fragment was used for the production of polyclonal antibodies specific for p70β<sup>S6k</sup>.

Construction of mammalian expression plasmids. The full length coding sequence, corresponding to the p70β-I (I-495 amino acids) was amplified by PCR using human cDNA clone N53 isolated from HEK293 library as a template and a panel of specific oligonucleotides. Amplified constructs were digested with appropriate enzymes, gel purified and cloned into the pcDNA1 vector in-frame with N-terminal FLAG epitope.

Amino-terminal EE-tagged p70α-II and p70β-II constructs were created by a PCR-based cloning strategy. This was achieved by using specific oligonucleotides containing EE-tag sequence and appropriate restriction sites. The cDNA encoding full length human p70β<sup>S6k</sup> (clone 53) and rat p70α<sup>S6k</sup> were used as templates. The resulting PCR fragments were digested with restriction enzymes, gel purified and cloned into the pcDNA3 expression vector. The construction of the pMT2 FLAG p70α-I was described previously (Hara et al., 1998). All constructs generated by a PCR-based approach were verified by sequencing. A Qiagen plasmid Midi kit was used to purify plasmid DNAs for transient transfections. The introduction of the FLAG-tag and the EE-tag sequences at the N-terminus of p70α<sup>S6k</sup> and p70β<sup>S6k</sup> allows the study of recombinant proteins via the use of specific antibodies.

Results. To test if the isolated p70β<sup>56k</sup> cDNA would encode a functional kinase capable of phosphorylating ribosomal protein S6, a cDNA fragment encoding a short version of p70β<sup>56k</sup> (p70β-II) was subcloned into mammalian expression vector in frame with EE-tag or Flag-tag epitopes. These constructs were transfected into HEK293 cells using lipofectAMINE under conditions recommended by the manufacturer. The

expression of recombinant p70 $\beta^{86k}$  was analyzed by immunoprecipatation or western blotting with EE-tag or Flag-tag antibodies. Both constructs express the protein of approximately 60kDa. The expression level of p70 $\beta^{86k}$  was comparable to that of p70 $\alpha$ -I and p70 $\alpha$ -II isoforms, when expressed in HEK293 cells.

Anti-p70β<sup>S6k</sup> polyclonal antibodies were generated using synthetic peptides corresponding to the carboxy terminal 15 amino acids of p70β<sup>S6k</sup>. These peptides were coupled to KLH and then injected into rabbits using standard procedures. Immune sera was purified using Affigel beads containing covalently cross-linked carboxy terminal peptide.

To determine whether the putative p70β<sup>s6k</sup> was indeed a novel ribosomal protein S6 kinase, the recombinant p70β<sup>s6k</sup> was expressed in HEK293 cells, immunoprecipitated with anti-EE-tag antibodies and an *in vitro* kinase reaction performed in the presence of purified 40S ribosomal subunit. As shown in Figure 4A, p70β<sup>s6k</sup> (p70β-II isoform) phosphorylates the S6 protein *in vitro* nearly as efficiently as p70α<sup>s6k</sup>. We also tested the ability of p70β<sup>s6k</sup> (p70β-II isoform) to phosphorylate a synthetic peptide representing C-terminus of S6 protein, which contains all sites known to be phosphorylated by p70α<sup>s6k</sup>. Figure 4B demonstrates that p70β<sup>s6k</sup> (p70β-II isoform) also phosphorylates this peptide but with slightly lower efficiency than observed with p70α<sup>s6k</sup>. Therefore, p70β<sup>s6k</sup> (p70β-II isoform) may not phosphorylate the same sites of the ribosomal protein S6 as does p70α<sup>s6k</sup>.

The intrinsic activity of the  $p70\beta^{S6k}$  is significantly lower than  $p70\alpha^{S6k}$ . The absence of one phosphorylation site in the autoinhibitory domain of  $p70\beta^{S6k}$  may be responsible for this decrease in intrinsic activity.

25

### EXAMPLE 4

Stimulation of p70β<sup>S6k</sup> Activity by insulin, serum and TPA

Materials and Methods. HEK293 cells or CHO-IR cells were transfected with plasmids containing  $p70\alpha^{86k}$  and  $p70\beta^{86k}$  sequences using lipofectAMINE under conditions recommended by the manufacturer (Gibco-BRL). Two days later.

transfected cells were frozen in liquid nitrogen and stored until lysis. After cell extraction, the lysates were subjected to immunoprecipitation and/or immunoblot analysis. If cells were to be stimulated, they were starved in medium without FCS for 16 h and then stimulated with 10<sup>-7</sup> M insulin for 10 min, 15% FCS for 10 min, 500 nM TPA for 30 min or vehicle alone. PAE-PDGF-R cells were transfected with appropriate plasmids using lipofectAMINE under conditions recommended by the manufacturer. After 24 h transfected cells were serum-starved for 16 h and stimulated with 20 ng/ml PDGF BB (Calbiochem) for 20 min. Control cells were treated with the vehicle under the same conditions.

Results. The effect of various extracellular stimuli on the p70β<sup>S6k</sup> activity was studied in different cell lines, transiently transfected with Flag-tagged or EE-tagged versions of p70β<sup>S6k</sup>. The activation of p70β<sup>S6k</sup> (p70β-II isoform) by insulin was analyzed in CHO-IR cells, which stably over expresses the insulin receptor. As shown in Figure 5A, treatment of CHO-IR cells with insulin induces p70β<sup>S6k</sup> (p70β-II isoform)
15 activity towards ribosomal S6 protein by 2.8 fold. In the same cell line and under the same conditions, the activity of p70α<sup>S6k</sup> was activated 3.5 fold with insulin treatment (Figure 5A). Almost equal amounts of p70α<sup>S6k</sup> and p70β<sup>S6k</sup> (p70β-II isoform) were expressed in cells and used in an *in vitro* kinase assay after immunoprecipitation. In addition, both serum and TPA also stimulated p70β<sup>S6k</sup> (p70β-II isoform)
20 phosphorylation of the ribosomal protein S6 (Figure 5A).

Using PAE-PDGF-R cells, the activation of the p70α<sup>S6k</sup> and p70β<sup>S6k</sup> (p70β-II isoform) by PDGF was examined. This cell line stably over expresses the PDGF receptor, and the activation of p70α<sup>S6k</sup> in response to PDGF was shown to be very efficient (Figure 5B). We found that PDGF stimulation of these cells leads to a rapid activation of recombinant p70β<sup>S6k</sup> (p70β-II isoform).

These data indicate that p70 $\beta^{S6k}$  is activated by a number of extracellular stimuli in a very similar way as p70 $\alpha^{S6k}$ . However, activation in the PAE-PDGF-R cells was 30 fold for p70 $\beta^{S6k}$  and only 3.4 fold for p70 $\alpha^{S6k}$ .

### **EXAMPLE 5**

## Effects of rapamycin and wortmannin on p70β<sup>S6k</sup> and p70α<sup>S6k</sup>

Materials and Methods. Treatment of transfected cells with rapamycin or wortmannin was performed as follows: 48 h after transfection, the cells were treated
with various concentrations of rapamycin or wortmannin for 30 min.

Results. These data in Examples 4 and 5 indicate that p70 $\beta$ <sup>S6k</sup> is activated by a number of extracellular stimuli in a similar fashion to  $p70\alpha^{s6k}$ . The two fungal inhibitors, wortmannin and rapamycin, specifically inhibit activation of p70 $\alpha^{S6k}$  via PI3-kinase- and mTOR-dependent pathways respectively. Thus, the effects of both 10 inhibitors on p70 $\beta$ <sup>S6k</sup> activity were examined. After p70 $\alpha$ -I and p70 $\beta$ -II were transiently expressed in HEK293 cells, cells were maintained in DMEM containing 10% FCS and then treated with various concentrations of rapamycin or wortmannin. We found that the activity of p $70\alpha^{S6k}$  and p $70\beta^{S6k}$  were inhibited by rapamycin and wortmannin in a dose dependent manner (Figures 6A and B, upper panel). However, it 15 appears that  $p70\beta^{S6k}$  is less sensitive to rapamycin and wortmannin, when compared with p70 $\alpha$ <sup>S6k</sup>. This difference is more obvious at lower concentration of inhibitors. In the presence of 20 nM rapamycin the inhibition of the p $70\alpha^{86k}$  is 92%, while only 46% for p70β<sup>S6k</sup>. Addition of 100 nM of wortmannin inhibits 86% of p70α<sup>S6k</sup> activity and 62% of p70β<sup>S6k</sup> activity. The inhibition of p70β<sup>S6k</sup> by rapamycin and wortmannin is 20 lower than that observed for  $p70\alpha^{S6k}$  indicating different mechanisms of regulation exist for p $70\beta^{86k}$ .

### EXAMPLE 6

## Interaction of the p70β<sup>S6k</sup> with different GST/SH3 fusion proteins

Materials and Methods. The EE-tag/p70 $\beta$ <sup>s6k</sup> was transiently over expressed in HEK293 cells as described above. Transfected cells were lysed in buffer A (50 mM-Tris/HCl pH = 8.0, 1% NP-40, 120 mM NaCl, 20 mM NaF, 1 mM EDTA, 6 mM EGTA, 20 mM sodium β-glycerophosphate, 1 mM DTT, 1 mM PMSF, 10 μg/ml leupeptin, 10 μg/ml pepstatin and 2 μg/ml aprotinin) two days after transfection. After

centrifugation at 12,000 rpm for 20 min, the supernatants were incubated for 2 hrs with Protein A beads pre-coupled with anti-EE antibodies. Beads were washed with lysis buffer before different GST/SH3 fusion proteins (1.5 mg each) were added to separate immunoprecipitation reactions. Two hours later, beads were washed extensively in

5 lysis buffer, bound proteins separated on the SDS-PAGE and transferred to the PVDF membrane. Specific interaction of the GST/SH3 domains with pre-bound EE-tag/p70β<sup>S6k</sup> was assessed by immunoblotting with the anti-GST antibodies.

Results. The C-terminus of the p70β<sup>S6k</sup> contains proline-rich sequences which are not present in p70α<sup>S6k</sup>. Src-homology region 3 domains (SH3 domain) are present
10 in many signaling and cytoskeletal molecules and interact specifically with proline-rich sequences which form left-handed helixes. Sequence analysis of the proline-rich region in p70β<sup>S6k</sup> indicates the presence of several putative SH3 domain binding motifs. Therefore, the ability of p70β<sup>S6k</sup> (p70β-II isoform) to interact with a panel of SH3 domains was examined. In this experiment, the EE-tag/p70β<sup>S6k</sup> was transiently over
15 expressed in HEK293 cells and immunoprecipitated with anti-EE antibodies coupled to Protein G Sepharose. The resulting immunoprecipitates were incubated with different GST/SH3 domain fusion proteins. After extensive washing, specific interaction between p70β<sup>S6k</sup> and SH3 domains was analyzed by SDS-PAGE and immunoblotting with anti-GST antibodies. As shown in Figure 7, several SH3 domains, including those
20 of GAP, Src, Fgr exhibited specific interaction towards p70β<sup>S6k</sup>.

### **EXAMPLE 7**

## Immunoprecipitation and Western blot analysis of transiently expressed p70 $\beta$ -I and . $p70\beta$ -II

25 Materials and Methods. Anti-p70β<sup>S6k</sup> polyclonal antibodies were generated using a synthetic peptide corresponding to the C-terminal tail of p70β<sup>S6k</sup>. The peptide was coupled to KLH, and rabbits were immunized using standard procedures. Immune sera harvested obtained from the immunized rabbits was purified using affinity chromatography on Affigel beads containing covalently cross-linked C-terminal

peptides of p70 $\beta$ <sup>S6k</sup>.

HEK293 cells were transfected with pcDNA1 along, pcDNA1/Flag-p70α-I, pcDNA1/Flag-p70β-I, or pcDNA1/Flag-p70β-II. Two days after transfection with one of these plasmids, cell lysates were prepared. Proteins were immunoprecipitated using the p70β<sup>S6k</sup> C-terminal affinity purified polyclonal antibodies or anti-Flag monoclonal antibodies. Immunoprecipitates were resolved on SDS PAGE and proteins transferred to PVDF membranes. The PVDF membranes were immunoblotted using anti-Flag monoclonal antibodies or p70β<sup>S6k</sup> C-terminal antibodies as indicated in Figure 8.

Results. The expression of both p70β<sup>s6k</sup> isoforms was analyzed in HEK293
10 cells using anti-p70β<sup>s6k</sup> C-terminus specific polyclonal antibodies. Both p70β<sup>s6k</sup> isoforms were found to be specifically immunoprecipitated with anti-p70β<sup>s6k</sup> antibodies, but not p70α-I, as confirmed by anti-Flag and anti-p70β<sup>s6k</sup> immunoblotting. It was found that the p70β-I isoform which encodes a 495 amino acid protein, is translated into a protein which migrates in a SDS-PAGE gel at approximately 70 kD.
15 The p70β-II isoform, which is a truncated form of p70β-I lacking 13 amino acids at the

amino terminus of p70β-II, migrates in a SDS-PAGE gel at approximately 60 kD.

### EXAMPLE 8

Generation of activated variants of p70 $\beta$ <sup>S6k</sup> (T401D) and p70 $\alpha$ <sup>S6k</sup> (T412D).

Materials and Method. Activated variants of p70β<sup>S6k</sup> and p70α<sup>S6k</sup> were made by site-directed mutagenesis. Oligonucleotide primers, specific to the site to be mutated and complimentary to opposite strands of p70β<sup>S6k</sup> and p70α<sup>S6k</sup> sequences were generated as recommended by manufacturer (Stratagene). Site-directed mutagenesis was carried out using pcDNA3/Glu-tag-p70β<sup>S6k</sup> and pcDNA3/Glu-tag-p70α<sup>S6k</sup>
 expression vector/plasmids as templates, according to the recommended protocol (Stratagene). All mutations were verified by DNA sequencing. Expression of mutated forms of both kinases was analyzed by immunobloting with anti-Glu-tag antibodies. The activity of normal and mutated forms of both kinases was measured by in vitro S6 kinase assay. 40S ribosomal subunit was used as a substrate in this reaction.

Results. Studies on p70α<sup>s6k</sup> demonstrate that this kinase is activated by multiple phosphorylations in response to growth factors or hormones (Fig. 9). A number of kinases that can phosphorylate p70α<sup>s6k</sup> in vitro and in vivo have been identified, including cdc2, MAPK, SAPK, p38, TOR and PDK1. However, very little is known about the process of dephosphorylation, which is essential for the inactivation of the kinase.

We have generated an activated form of p70β<sup>S6k</sup> by substituting putative phosphorylation site Thr 401 with Aspartic acid (Asp) ("p70β<sup>S6k</sup> (T402D)") as shown in Fig 10. Transfection studies in HEK293 cells and S6 kinase assays indicated that p70β<sup>S6k</sup> (T401D) mutant is in an activated state in unstimulated cells, when compared with wild type kinase (3 times higher activity, as shown in Fig 11). We have also created an activated version of p70α<sup>S6k</sup> (T412D), which showed a greater state of activation (18 fold activation, Fig. 12).

It will be apparent to the skilled artisan that activated variants of both kinases such as disclosed above can be used in the search for binding partners. Binding partners or molecules, such as phosphatases, are considered to form tighter and more stable complexes with such irreversibly activated kinases.

## **EXAMPLE 9**

## Identification of p70β<sup>S6k</sup>-binding partners.

Materials and Methods. HEK293 cells are transfected using lipofectAMINE (as recommended by manufacturer, Gibco-BRL) with pcDNA3 expression vectors encoding activated variants of p70β<sup>S6k</sup> (T401D) and p70α<sup>S6k</sup> (T412D). Binding partners that preferentially associate with p70β<sup>S6k</sup> may be identified by comparing the profile of proteins precipitated from activated p70β<sup>S6k</sup> expressing cells to the profile of activated p70α<sup>S6k</sup> expressing cells and/or negative control cells. Cells transfected with the pcDNA3 plasmid alone, may be used as a negative control in this experiment. Two days after transfection, cells are lysed in extraction buffer: 50 mM Tris/HCl (pH8.0); 120 mM NaCl; 20 mM NaF; 20 mM b-glycerophosphate; 1 mM EDTA, (pH 8.0); 6

WO 00/08173 PCT/US99/17595

mM EGTA; 1% NP-40; 1 mM DTT. The following protease and phosphatase inhibitors are added to the extraction buffer just before cell lysis: 5 mM Benzamidine; 1 mM PMSF; 1mg/ml of aprotinin; 0.125 mM NaVO4; Pepstatin; and Leupeptin.

The resulting cell lysate is centrifuged at 14,000 rpm for 20 min at 4°C to

5 remove the insoluble fraction. If the lysate is not used immediately it is stored at -80°C until needed. The protein concentration of the samples is measured using a Coomassie Protein Assay reagent (Pierce) at 595 nm. An equal amount of supernatant from each sample is added to fresh 1.5 ml tubes and the volumes is equalized using lysis buffer. Affinity purified anti-Glu antibody is added to the supernatant and incubated on the

10 wheel for 1 hr at 4°C. Protein-G sepharose beads, pre-washed in lysis buffer, are used to bring down immune complexes.

After extensive washing in lysis buffer (4x), 2x sample buffer is added to the beads. Bound proteins are eluted from the beads by boiling and separated by SDS-PAGE electrophoresis. Separated proteins are silver stained and the pattern of associated proteins is analyzed.

**Results.** The pattern of associated proteins are compared between activated variants of  $p70\beta^{S6k}$  and  $p70\alpha^{S6k}$  kinases. Mutated variants of both kinases are transiently expressed in HEK293 cells as Glu-tag fusion proteins. The presence of a Glu-tag epitope at the N-terminus of  $p70\beta^{S6k}$  and  $p70\alpha^{S6k}$  allows specific

20 immunoprecipitation of activated kinases from transfected cells. The skilled practioner will recognize that the Glu-tag fusion is not necessary to the invention and that similar results could be obtained with antibodies specific to each or both of the activated variants in the absence of a fusion epitope.

The skilled practioner will recognize that binding partners or polypeptides that preferentially bind to activated P70β<sup>S6K</sup> can be isolated by one or more standard techniques such as immunoprecipitation, hplc, fplc, column chromatography or preparative electrophoresis.

Although the present invention has been described in detail with reference to examples above, it is understood that various modifications can be made without

departing from the spirit of the invention. Accordingly, the invention is limited only by the following claims. All cited patents and publications referred to in this application are herein incorporated by reference in their entirety.

### WHAT IS CLAIMED:

- 1. An isolated nucleic acid molecule selected from the group consisting of a nucleic acid molecule comprising the sequence of SEQ ID No.1 (the nucleotide sequence of the  $p70\beta^{S6k}$ ); and a nucleic acid molecule which encodes a  $p70\beta^{S6k}$  and which hybridizes to a nucleic acid molecule having the sequence of SEQ ID No.1 under stringent conditions.
- 2. An isolated nucleic acid molecule which encodes a protein having SEQ ID No.2 (the  $p70\beta^{S6k}$ ) or a protein having one or more conservative amino acid substitutions in SEQ ID No.2.
- 3. An isolated nucleic acid molecule selected from the group consisting of a nucleic acid molecule comprising the sequence of SEQ ID No.1 (the nucleotide sequence of the  $p70\beta^{S6k}$ ); a nucleic acid molecule which encodes a  $p70\beta^{S6k}$  and which hybridizes to a nucleic acid molecule having the sequence of SEQ ID No.1 under stringent conditions, and a nucleic acid molecule at least about 65% sequence identity with SEQ ID No.1.
- 4. An isolated nucleic acid molecule which encodes a protein having SEQ ID No.2 (the p70 $\beta$ <sup>S6k</sup>), a protein with at least 75% identity to SEQ ID No.2, or a polypeptide fragment of SEQ ID No.2.
- 5. An isolated polypeptide which phosphorylates a ribosomal S6 protein and is encoded by a nucleic acid molecule of claim 1 or claim 2.
- 6. A method of identifying an agent which modulates  $p70\beta^{S6k}$  mediated phosphorylation of a ribosomal S6 subunit comprising the steps of: exposing  $p70\beta^{S6k}$  and a ribosomal S6 subunit to the agent; and

determining whether the agent modulates  $p70\beta^{86k}$  mediated phosphorylation of the ribosomal S6 subunit.

- 7. A method of modulating protein synthesis or cellular proliferation comprising the step of administering an agent which modulates  $p70\beta^{56k}$  phosphorylation of a ribosomal S6 subunit.
- 8. A method of identifying an agent that modulates a kinase or a phosphatase induced regulation of  $p70\beta^{S6k}$  activity comprising the steps of: exposing  $p70\beta^{S6k}$  and the kinase which phosphorylates  $p70\beta^{S6k}$  to an agent; and determining whether the agent modulates the kinase or the phosphatase induced regulation of  $p70\beta^{S6k}$  activity.
- 9. The method of claim 8, wherein the kinase which phosphorylates  $p70\beta^{S6k}$  is PKC.
- 10. A method of modulating protein synthesis or cellular proliferation comprising the step of administering an agent which modulates the phosphorylation of  $p706^{86k}$ .
- 11. A method of modulating cell cycle comprising the step of administering an agent which regulates the ability  $p70\beta^{S6k}$  to bind with a ligand.
- . 12. An antibody or antibody fragment which specifically binds to an epitope of  $p70\beta^{S6k}$ .
- 13. The antibody of claim 11, wherein the antibody is selected from the group consisting of a monoclonal antibody, human antibody, chimeric antibody, and humanized antibody.

- 14. An antibody of claim 11 wherein the epitope is a proline rich epitope of a p70 $\beta$ <sup>S6k</sup> protein.
- 15. A fusion protein comprising SEQ ID No.2 or a polypeptide fragment thereof fused to a heterologous protein.
  - 16. A cell transformed with a nucleic acid molecule of any of claims 1-3.
  - 17. A method of identifying a substrate of  $p70\beta^{S6k}$  comprising the steps of: exposing  $p70\beta^{S6k}$  or a polypeptide fragment thereof to an agent; and determining whether  $p70\beta^{S6k}$  binds to the agent.
- 18. A method of identifying a substrate of p70β<sup>s6k</sup> comprising the steps of: forming a mixture comprising p70β<sup>s6k</sup> and a candidate agent; incubating said mixture under conditions conducive to phosphorylation by p70β<sup>s6k</sup>; and determining whether the candidate agent is phosphorylated.
  - 19. A method of indentifying binding partners of p70 $\beta^{S6K}$  comprising the step of incubating a first cellular extract with p70 $\beta^{S6K}$ , activated variants of p70 $\beta^{S6K}$  or a fusion protein of claim 15.
  - 20. The method of claim 19 further comprising incubating a second cellular extract with  $p70\alpha^{S6K}$ , activated variants of  $p70\alpha^{S6K}$  or a fusion protein of  $p70\alpha^{S6K}$  and comparing the first and second cellular extracts.
  - 21. A method of indentifying binding partners of p70β<sup>S6K</sup> comprising the step of isolating a first a first cellular extract from a cell containing p70β<sup>S6K</sup>, activated variants of p70β<sup>S6K</sup> or a fusion protein of claim 15.

- 22. The method of claim 19 further comprising isolating a second cellular extract from a cell containing  $p70\alpha^{S6K}$ , activated variants of  $p70\alpha^{S6K}$  or a fusion protein of  $p70\alpha^{S6K}$  and comparing the first and second cellular extracts.
- 23. An isolated polypeptide comprising an activated p70 $\beta$ <sup>S6k</sup>.
- 24. The isolated polypeptide of claim 23 further comprising a mutation of Threonine 401 to Aspartic acid.
- 25. An isolated polypeptide that preferentially binds to an activated p70 $\beta$ <sup>S6K</sup> of claim 23.
- 26. The isolated polypeptide of claim 25 that preferentially binds to an activated  $p70\beta^{S6k}$  of claim 24.
- 27. An antibody or antibody fragment that specifically binds to the isolated polypeptide of claims 25 or 26.
- 28. A method of determining whether a cell expresses aberrant cellular levels of  $p70\beta^{S6k}$  comprising:
  - (a) determining the level of  $p70\beta^{\text{S6k}}$  in a normal cell type;
  - (b) determining the level of  $p70\beta^{S6k}$  in a test cell;
  - (c) comparing the level of  $p70\beta^{S6k}$  in the normal cell to the  $p70\beta^{S6k}$  level in the test cell.
- 29. The method of claim 28 wherein the level of  $p70\beta^{S6k}$  is determined by finding the level  $p70\beta^{S6k}$  RNA in a cell.

WO 00/08173 PCT/US99/17595

30. The method of claim 28, wherein the level of  $p70\beta^{S6k}$  is determined by finding the level of  $p70\beta^{S6k}$  protein in a cell.

- 31. A method of determining whether a cell expresses aberrant cellular levels of a p70 $\beta^{S6k}$  binding partner comprising:
  - (a) determining the level of said binding partner in a normal cell;
  - (b) determining the level of said binding partner in a test cell;
  - (c) comparing the level of said binding partner in the normal cell to the binding partner level in the test cell.
- 32. A vector comprising the isolated nucleic acid of claim 2, operably linked to a promotor or transcription.
- 33. The vector of claim 32, further comprising one or more enhancers or upstream activating sequences.
- 34. The vector of claim 32, wherein the vector comprises pcDNA3.
- 35. A vector which encodes an activated p70β<sup>S6k</sup> of claims 23 or 24.
- 36. A DNA vector comprising a nucleic acid encoding a p $70\beta^{86k}$  or an activated p $70\beta^{86k}$  fusion protein.
